ABSTRACT

The effects of trim on stability of motion during depth control of submersible vehicles are analysed. Full state feedback control is used to provide stable response in the dive plane, and feedforward control is used to ensure steady state accuracy. A comple so of stability maps is generated for various values of meta entric height, longititunal center of gravity/center of buoyancy separation, forward speed, and control law time constant. The results clearly indicate ranges of parameters that should be chosen in design and operation of a given vehicle.

I. INTRODUCTION

The fundamental goal of submarine control is to reach and maintain ordered depth. Experimental designs involve expensive model testing such as Darpa Suboff Model (DTRC Model 5470) [Ref. 6]. Much research has been done in depth control of submarines [Ref. 3,5]. Our goal is to develop an analytic method to determine the stability properties of a design.

The stability of a design will have a significant impact on its responsiveness. A vehicle with a large margin to instability will not be very responsive. The problem becomes one of determining how close to the margins we can get without a total loss of stability. By expanding the scope of our research to include nonlinear terms we are able to define the limits of stability and therefore margins.

Previous studies analyzed stability properties of the system, specially static bifurcations [Ref. 2] and bifurcations to periodic solutions [Ref. 1]. The latter study which is used as a basis for this work, was restricted to level, zero trim flight paths.

The purpose of this thesis is to develop a program for finding the limits of stability for an out of trim submarine at moderate and high speeds. These limits are mapped using a Hopf bifurcation analysis program included in the Appendix.

II. EQUATIONS OF MOTION

The motion of the submersible in the vertical plane can be modeled by four coupled nonlinear differential equations for pitch rate (q), heave velocity (w), pitch angle (θ) and heave (z). With a body fixed coordinate frame at the vehicle's geometric center, we can express Newton's equations of motion as

$$m (\dot{w} - Uq - z_G q^2 - x_G \dot{q}) = Z_{\dot{q}} \dot{q} + Z_{\dot{w}} \dot{w} + Z_{\dot{b}_b} \delta_b + Z_z \delta_z + Z_{\dot{w}} w + Z_{\dot{q}} q$$

$$-\frac{1}{2} \rho \int C_D b(x) \frac{(w - xq)^3}{|w - xq|} dx$$
(2.1)

$$I_{y} - m x_{G}(\dot{w} - Uq) - z_{G}w q m = -x_{GB}B\cos\theta - z_{GB}B\sin\theta + M_{\delta_{i}}\delta_{z}$$

$$M_{\delta_{i}}\delta_{b} + M_{d}\dot{q} + M_{w}\dot{w} + M_{q}q + M_{w}w + \frac{1}{2}\rho \int C_{D}b(x) \frac{(w - xq)^{3}}{|w - xq|} xdx$$
(2.2)

$$\dot{\theta} = q \tag{2.3}$$

$$\dot{z} = -U\sin\theta + w\cos\theta \tag{2.4}$$

Equations 2.1 through 2.2 can be written in a more compact form as,

$$\dot{w} = a_{11}Uw + a_{12}Uq + a_{13}z_{GB}\sin\theta + a_{13}x_{GB}\cos\theta + b_{1}U^{2}\delta_{z}$$

$$b_{2}U^{2}\delta_{b} + d_{w}(w,q) + c_{1}(w,q)$$
(2.5)

$$\dot{q} = a_{21}Uw + a_{22}Uq + a_{23}z_{GB}\sin\theta + a_{23}x_{GB}\cos\theta + b_{1}U^{2}\delta_{z}$$

$$b_{2}U^{2}\delta_{b} + d_{q}(w,q) + c_{2}(w,q)$$
(2.6)

where,

$$\begin{split} D_{v} &= (m - Z_{w}) (I_{y} - M_{d}) - (mx_{G} + Z_{d}) (mx_{G} + M_{w}) \\ a_{11}D_{v} &= (Z_{w} - 2C_{D}E_{0}Utan \; \theta_{0}) (I_{y} - M_{d}) + (mx_{G} + Z_{d}) (M_{w} + 2C_{D}E_{1}Utan \; \theta_{0}) \\ a_{12}D_{v} &= (m + Z_{q} + 2C_{D}E_{1}Utan \; \theta_{0}) (I_{y} - M_{d}) + \\ (mx_{G} + Z_{d}) (M_{q} - mx_{G} - mz_{G}Utan \; \theta_{0} - 2C_{D}E_{2}Utan \; \theta_{0}) \\ a_{21}D_{v} &= (M_{w} + 2C_{D}E_{1}Utan \; \theta_{0}) (m - Z_{w}) + (mx_{G} + M\psi)(Z_{w} - 2C_{D}E_{0}Utan \; \theta_{0}) \\ a_{22}D_{v} &= (M_{q} - mx_{G} - mz_{G}Utan \; \theta_{0} - 2C_{D}E_{2}Utan \; \theta_{0}) \\ (mx_{G} + M_{w}) (m + Z_{q} + 2C_{D}E_{1}Utan \; \theta_{0}) \\ a_{23}D_{v} &= -(m + Z_{w})B \end{split} \tag{2.7}$$

$$\begin{split} b_2 D_v &= (m - Z_\psi) M_\delta + (m x_G + M_\psi) Z_\delta \\ d_q(w, q) D_v &= (m - Z_\psi) I_q + (m x_G + M_\psi) I_w \\ d_w(w, q) D_v &= (I_y - M_q) I_w - (m x_G + Z_q) I_q \\ c_1(w, q) D_v &= (I_y - M_q) m z_G q^2 - (m x_G + Z_q) m z_G wq \\ c_2(w, q) D_v &= -(m - Z_\psi) m z_G wq - (m x_G + M_\psi) m z_G q^2 \end{split}$$

In these equations the submersible is assumed to be neutrally buoyant (W=B), and statically stable $(z_G > z_B)$. Here we can assume z_B to be zero, hence $z_{GB} = z_G$.

At steady state the cross flow drag integral terms I_n and I_n have the form,

$$I_H = -C_D w |w| \int b(x) dx$$
 $I_P = C_D w |w| \int b(x) x dx$ (2.8)

From equation (2.3) it is seen that w is equal to $\tan\theta_0$ at steady state. The /b(x)dx term is computed numerically for the SUBOFF model as E_0 , and /b(x)xdx term as E_1 . Therefore, the cross flow drag terms become,

$$I_{H} = -C_{D} w /w / E_{O}$$
 $I_{P} = C_{D} w /w / E_{I}$ (2.9)

Because we have two rudders at the bow and the stern, our system of equations is multi-input. To reduce this system into a single input system the linear combination of the control inputs will be modified into the following form,

$$\delta = \delta_a \quad , \quad \delta_b = \alpha \delta_a \tag{2.10}$$

where α is the control surface coordination gain. The value of α ranges from -1 to 1. The selection of the value of α will allow the planes to operate as desired for the particular maneuvering condition, i.e., $\alpha=0$ for no bow plane control, $\alpha=-1$ for bow plane and stern plane opposed to each other, yielding the maximum pitch moment, and $\alpha=1$ for bow and stern plane control in the same direction, yielding the maximum heave force.

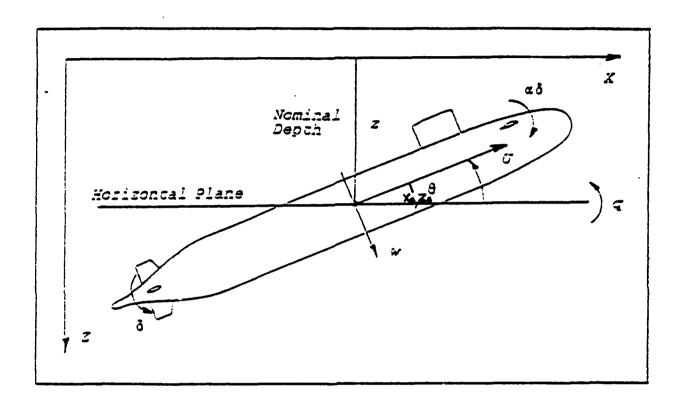

FIGURE 2.1 Geometric representations of the basic definitions.

III. CONTROL LAW

A. INTRODUCTION

The control design problem can be expressed in state space as follows,

$$\dot{x} = Ax + B\delta \tag{3.1}$$

where the state vector is

$$x = \begin{bmatrix} \theta \\ w \\ q \\ z \end{bmatrix}$$
 (3.2)

Equation 3.1 in our case is,

$$\begin{bmatrix} \dot{\theta} \\ \dot{w} \\ \dot{q} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ a_{13}z_{GB} - b_{1}u^{2}k_{1} & a_{11}u - b_{1}u^{2}k_{2} & a_{12}u - b_{1}u^{2}k_{3} & -b_{1}u^{2}k_{4} \\ a_{23}z_{GB} - b_{2}u^{2}k_{1} & a_{21}u - b_{2}u^{2}k_{2} & a_{22}u - b_{2}u^{2}k_{3} & -b_{2}u^{2}k_{4} \\ -u & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \theta \\ w \\ q \\ z \end{bmatrix}$$

$$(3.3)$$

Our aim is to find a controller which will assure us a stable closed loop system. The only control input is the dive plane angle, δ .

B. FEEDBACK CONTROL

1. Pole Placement

The full state feedback controller is a linear function of the states and has the form,

$$\delta = -K x \tag{3.4}$$

where K is the vector of feedback gains which are to be determined in order to give the desired closed loop system dynamics. Substituting equation 2.12 into 2.10 yields,

$$\dot{\mathbf{r}} = (A - BK)\mathbf{r} \tag{3.5}$$

The feedback gains K must be chosen such that A - BK has the desired eigenvalues. The actual characteristic equation of the closed loop system is given by,

$$det(A - BK - sI) = 0 (3.6)$$

The required values of K are obtained by matching coefficients in the two polynomials of the actual and the desired characteristic equations. Equation 3.5 becomes,

$$\begin{bmatrix} \dot{\theta} \\ \dot{w} \\ \dot{q} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ a_{13}z_{GB} & a_{11}u & a_{12}u & 0 \\ a_{23}z_{GB} & a_{21}u & a_{22}u & 0 \\ -u & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \theta \\ w \\ q \\ z \end{bmatrix} + \begin{bmatrix} 0 \\ b_{1}u^{2} \\ b_{2}u^{2} \\ 0 \end{bmatrix} \delta$$
(3.7)

The characteristic equation of the closed loop system is,

$$\det\begin{bmatrix} -s & 0 & 1 & 0 \\ a_{13}z_{GB} - b_{1}u^{2}k_{1} & a_{11}u - b_{1}u^{2}k_{2} - s & a_{12}u - b_{1}u^{2}k_{3} & -b_{1}u^{2}k_{4} \\ a_{23}z_{GB} - b_{2}u^{2}k_{1} & a_{21}u - b_{2}u^{2}k_{2} & a_{22}u - b_{2}u^{2}k_{3} - s & -b_{2}u^{2}k_{4} \\ -u & 1 & 0 & -s \end{bmatrix}$$

$$(3.8)$$

which reduces to,

$$s^{4} + (A_{2}k_{2} + A_{3}k_{3} - E_{1})s^{3} + (-B_{1}k_{1} - B_{2}k_{2} - B_{3}k_{3} - B_{4}k_{4} - E_{2})s^{2} + (-C_{1}k_{1} - C_{2}k_{2} - C_{3}k_{3} - E_{3})s + (-D_{1}k_{4} - D_{2}k_{4}) = 0$$
(3.9)

where,

$$A_2 = -B_4 = b_1 u^2$$

$$A_3 = -B_1 = b_2 u^2$$

$$B_2 = (a_{22} b_1 - a_{12} b_2) u^3$$

$$B_3 = C_1 = (a_1, b_2 - a_2, b_1) u^3$$

$$C_2 = D_1 = (a_{23} \ b_1 - a_{13} \ b_2) \ z_{aa} \ u^2$$
 (3.10)

$$C_4 = (a_{22} b_1 + b_2 - a_{12} b_2) u^3$$

$$D_2 = (a_{11} b_2 - a_{21} b_1) u^4$$

$$E_1 = (a_{11} + a_{22}) u$$

$$E_2 = a_{23}Z_{GB} + (a_{12}a_{21} - a_{11} a_{22}) u^2$$

$$E_3 = (a_{13} \ a_{21} - a_{11} \ a_{23}) \ z_{GB} \ u$$

Now, let's assume that we want to place the closed loop poles at $-p_1$, $-p_2$, $-p_3$, $-p_4$ to have the desired system response. Then the desired characteristic equation is,

$$s^4 + \alpha_1 s^3 + \alpha_2 s^2 + \alpha_5 s + \alpha_4 = 0 \tag{3.11}$$

where,

$$\alpha_{1} = p_{1} + p_{2} + p_{3} + p_{4}$$

$$\alpha_{2} = p_{1}p_{2} + p_{1}p_{3} + p_{1}p_{4} + p_{2}p_{3} + p_{2}p_{4} + p_{3}p_{4}$$

$$\alpha_{3} = p_{1}p_{2}p_{3} + p_{1}p_{2}p_{4} + p_{1}p_{3}p_{4} + p_{2}p_{3}p_{4}$$
(3.12)

 $\alpha_4 = p_1 p_2 p_3 p_4$

The feedback gains can now be computed by equal g the coefficients of equation 3.9 and 3.11,

$$A_{2} k_{2} + A_{3} k_{3} = -\alpha_{1} - E_{1}$$

$$B_{1} k_{2} + B_{2} k_{2} + B_{3} k_{3} + B_{4} k_{4} = \alpha_{2} + E_{2}$$

$$C_{1} k_{1} + C_{2} k_{2} + C_{4} k_{4} = \alpha_{3} + E_{3}$$

$$(D_{1} + D_{2}) k_{4} = \alpha_{4}$$

$$(3.13)$$

We established the method for placing the poles of the system, but we also need to know the desired locations of the poles.

2. Pole Location Selection

In a typical second order system control law design, transient response specifications are given. This results in an allowable region in the s-plane where the desired location of the poles can be obtained. For higher order systems the concept of dominant roots can be employed. In selecting poles the physics of the system must be considered. If the poles are too negative, a small time constant will result, and the system may not be able to react that fast. If we use big gains

K, this also means that the control effort will be large. In practice there are limits based on actuator size and saturation.

Considering the control law design to stabilize the surmarine to a level flight path at $\theta=0$ it is required that the submarine return to the level flight, after some small disturbances in θ or z, within the time it takes for the vehicle to travel three ship lengths. Since our model is 14 feet long and its velocity is 5 feet/sec., the required recovery time is about 10 seconds. This means the time constant is 3 seconds and the closed loop poles should be placed at approximately -0.3.

After placing the poles using equation 3.13 the control law is found to be,

$$\delta = 0.9917 \ \theta + 0.8333 \ w + 0.6026 \ q - 0.0351 \ z \tag{3.14}$$

C. FEEDFORWARD CONTROL

The previous discussion on feedback controller assures closed loop stability, but it acts as a regulator in other words takes all the states to zero values. If we have constant disturbances or we want to track some reference value other than zero we can not do this with state feedback alone.

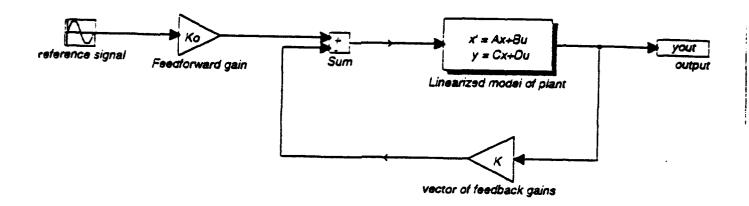

FIGURE 3.1 Feedback and feedforward control application to our linearized model

In the case of non-zero set points or constant disturbances we again need to have the exact same full state feedback to ensure closed loop stability. But we also need to introduce an additional term to our controller in the form

$$u = -K x + k_0 (3.15)$$

where ko is the constant feedforward term. ko is given as [Ref. 4],

$$k_o = H_c^{-1}(0) x_o (3.16)$$

where x_0 is the reference values of the states and $H_c^{-1}(s)$ is the closed loop transfer function,

$$H_c^{-1}(s) = C (sI - A + BK)^{-1} B$$
 (3.17)

Another way of getting k_0 is looking at the steady state equations of motion. In steady state all the time derivatives in equations 2.1 through 2.4 go to zero and we have,

$$w = \tan \theta_0 \tag{3.18}$$

$$(3.19)$$

$$Z_{\bullet}\delta + Z_{\bullet}w - I_{H} = 0$$

$$-(x_G - x_B)B\cos\theta_0 - z_{GB}B\sin\theta_0 + M_b\delta + M_ww + I_p = 0$$
 (3.20)

If the equation 3.19 is multiplied with M_{δ} and equation 3.20 with Z₈ and set equal to each other and plug in the equation 3.18, we have an equation depending only on θ .

$$(Z_{w}M_{b} - M_{w}Z_{b}) \tan \theta_{0} + x_{G}B Z_{b}\cos \theta_{0} + z_{G}B Z_{b}\sin \theta_{0} + C_{D}(E_{0}M_{b} - E_{1}Z_{b}) \tan \theta_{0} | \tan \theta_{0}|$$

$$(3.21)$$

Where \mathbf{E}_0 and \mathbf{E}_1 are the integral terms computed numerically for Suboff model. The steady state value of θ_0 is from equation 3.20 by using a Newton-Raphson method found in Bifurl program in the Appendix. Then we can get δ from equation 3.19,

$$\delta = \frac{I_H - Z_w w}{Z_b} = \frac{-C_D E_0 \tan \theta_0 |\tan \theta_0| - Z_w w}{Z_b}$$
 (3.22)

After getting δ , we easily find k_{o} from equation 3.15,

$$k_o = \delta + Kx \tag{3.23}$$

A plot of the steady state angle θ_o versus x_c for different values of z_c is shown in Figure 3.2.

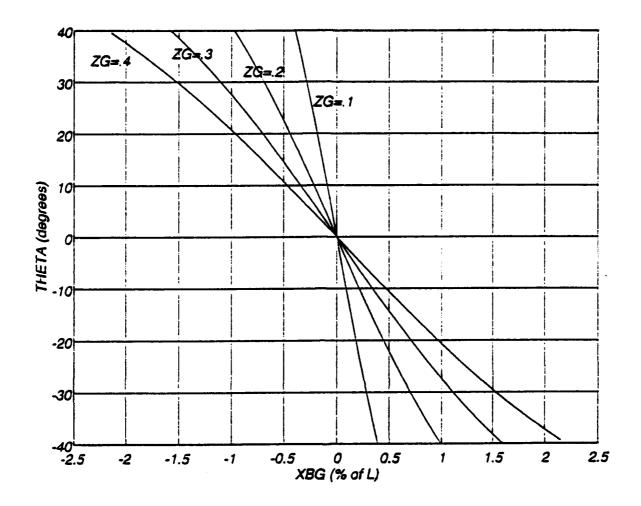

FIGURE 3.2 Steady state pitch angle $\boldsymbol{\theta}_o$ as metacentric height varies

IV. BIFURCATION ANALYSIS

A. STABILITY

The nonlinear equations of motion in the dive plane 2.1 through 2.4 can be expressed in a compact form as follows,

$$\dot{x} = f(x) \tag{4.1}$$

Where x is the state variable vector $x=[\theta,w,q,z]$. We know that the equilibrium points, x_0 of the system are defined by,

$$f(x_0) = 0 ag{4.2}$$

This is a nonlinear system of algebraic equations and it may have multiple solutions in x_0 , which means that the nonlinear system may have more than one positions of static equilibrium. If we pick one equilibrium, x_0 we can establish its stability properties by linearization. The linearized system becomes,

$$\dot{x} = Ax \tag{4.3}$$

where A is the Jacobian matrix of f(x) evaluated at x_0 ,

$$A = \frac{\partial f}{\partial x} \tag{4.4}$$

and the state has been defined to designate small deviations from the equilibrium x_0 ,

$$x \rightarrow x - x_0 \tag{4.5}$$

In system dynamics as long as all eigenvalues of A have negative real parts, we know that the linear system will be stable. This means that the equilibrium \mathbf{x}_0 will be stable for the nonlinear system as well. This is in fact Lyapunov's linearization technique.

B. BIFURCATION

Values of the nonlinear system parameters at which the qualitative nature of the system's motion changes are known as critical or bifurcation values. The phenomena of bifurcation, i.e., quantitative change of parameters leading to qualitative change of system properties, is the topic of bifurcation theory. Euler buckling (Pitchfork bifurcation), limit cycles (Hopf bifurcation) are common examples of bifurcation.

Classical definition of stability states, that the real part of all the eigenvalues of the system must be negative. Therefore, our initial investigations into the stability of the SUBOFF model was to find those eigenvalues whose real parts cross the imaginary axis. We used the bifurcation analysis program, included in the Appendix, to calculate the eigenvalues of the system.

By linearizing the equations of motion, equations 2.1 through 2.4, the state space equations of the dynamic system can be written in the form,

$$\dot{x} = Ax + Bu \tag{4.5}$$

where,

$$u = -Kx \tag{4.6}$$

and K is the vector of controller gains, as calculated by pole placement in equations 3.13. The eigenvalues of the system are found by solving,

$$det|A-BK-sI| = 0 (4.7)$$

In the bifurcation program a pseudo-root locus method is employed where the time constant, T_c , is fixed. The constant T_c fixes to placement of the system poles at a given nominal forward speed U_0 and then the model speed, U, is varied incrementally with the system eigenvalues calculated at each speed increment. When the real part of an eigenvalue changes sign between the limits of a speed increment a bisection method is employed to find the speed where the real part of the eigenvalue equals zero.

For each point where the real part of an eigenvalue crosses the imaginary axis the associated \mathbf{T}_c and \mathbf{U} are plotted on a bifurcation map. This map delineates the regions of

classical stability (all eigenvalues on the left hand plane) from the regions of instability. A family of bifurcation maps were generated by varying nominal speed, U_0 , initial stability, $z_{\rm GB}$, and longitudinal center of gravity/buoyancy separation, $x_{\rm GB}$ of the submersible.

Figure (4.1) shows a typical bifurcation map with its five distinct regions [Ref. 1]. Region I is the area of classical stability. In region II there is one real positive eigenvalue which is indicative of a pitchfork bifurcation. Pitchfork bifurcations of this model were previously examined by Reidel [Ref. 1]. Regions III, IV, and V have at least one pair of complex conjugate eigenvalues with a positive real part. This would indicate that there should be an unstable oscillatory behavior for the model.

C. RESULTS AND DISCUSSION

The classical stability region in bifurcation maps lies between pitchfork and Hopf bifurcation boundaries. The limits or parameters must be defined for the system designer prior to starting the design. By maximizing the region of stability we can give the designer the most leeway in his work. There are

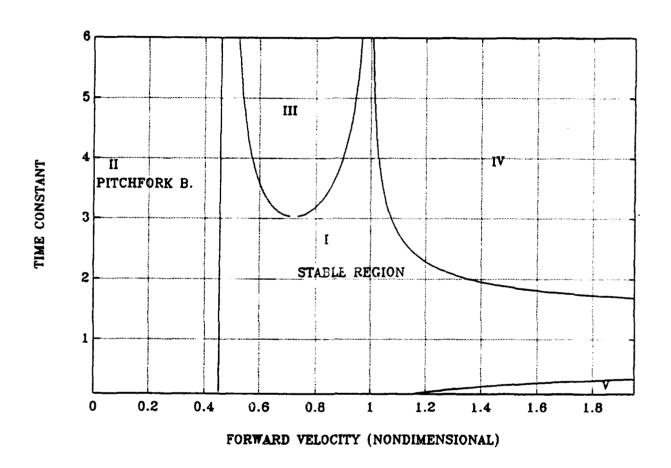

FIGURE 4.1 A typical bifurcation map showing the five distinct regions

two parameters that we used to change the bifurcation maps, the longitudinal separation between center of gravity and center of buoyancy, x_{GB} and the initial stability, z_{GB} .

First we look at the change in x_{GB} . In figures 4.2 through 4.7 we plotted bifurcation curves for different initial stabilities as x_{GB} varies. We can see that as x_{GB} increases the Hopf bifurcation branches H1 an H2 move towards higher speeds and time constants and thus increasing the stability area. The H3 branch however remains constant.

The other important point that we observed is that the system becomes unstable at nominal speed at higher time constants. This is unexpected because we are designing around our nominal speed. A more careful examination in the trimmed case shows that the actual forward velocity becomes, $\sqrt{u^2+w^2}$. Therefore the system may become stable at a value of u other than nominal.

The next parameter we examined was the initial stability, z_{GB} . Figures 4.8 through 4.14 show the effect of varying z_{GB} from .2 to .4 ft for different x_{GB} values. The H3 branch remains constant while the upper speed H2 branch moves down effectively decreasing the area of stability. The low speed curve H1 moves upwards and increases the low speed area of stability.

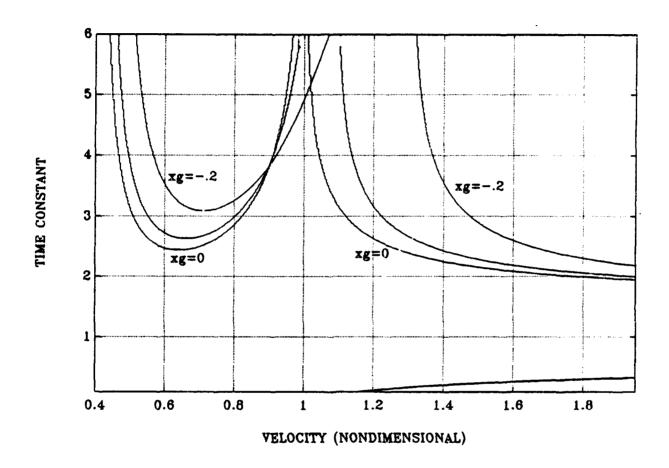

FIGURE 4.2 Bifurcation map as xg changes between xg=0 and xg=-.2, zg=.2.

V. CONCLUSIONS AND RECOMMENDATIONS

A. CONCLUSIONS

Hopf bifurcation analysis is a very useful design tool in the design and evaluation phase. Hopf bifurcation analysis and an identification program that can evaluate the hydrodynamic coefficients for the submersible vehicle will be very useful and save money and time by reducing the amount of model testing. An effective set of control system parameters can be generated in this process that will be optimal for the final design of the submersible.

This type of analysis can set the limits of the ranges of metacentric height important parameters such as longitudinal separation of buoyancy/gravity centers. As we have seen changes in these two parameters can have dramatic effects on stability. It was found that the moderate speed region of stability increases with increasing metacentric height. The same is not true, however, for high speeds. The longitudinal separation of center of gravity/buoyancy can have a profound effect on stability. It was found that the vehicle may be unstable even at nominal speed. This was attributed to the fact that at high trim angles, the feedback gains which are computed at zero trim, can no longer guarantee stability.

B. RECOMMENDATIONS

The bifurcation analysis program should be expanded to evaluate the performance of the submarine including effects of external forces such as wave effects, currents, and free surface effects.
